#### 1. Problem Statement

Janani is a tech enthusiast who loves working with polynomials. She wants to create a program that can add polynomial coefficients and provide the sum of their coefficients.

The polynomials will be represented as a linked list, where each node of the linked list contains a coefficient and an exponent. The polynomial is represented in the standard form with descending order of exponents.

### **Input Format**

The first line of input consists of an integer n, representing the number of terms in the first polynomial.

The following n lines of input consist of two integers each: the coefficient and the exponent of the term in the first polynomial.

The next line of input consists of an integer m, representing the number of terms in the second polynomial.

The following m lines of input consist of two integers each: the coefficient and the exponent of the term in the second polynomial.

#### **Output Format**

The output prints the sum of the coefficients of the polynomials.

```
Input: 3
22
 3 18
40
 22
3 1
40
Output: 18
Answer
// You are using GCC
#include <stdio.h>
#include <stdlib.h>
typedef struct Node {
int coefficient;
  int exponent;
   struct Node* next;
} Node:
Node* createNode(int coefficient, int exponent) {
  Node* newNode = (Node*)malloc(sizeof(Node));
   newNode->coefficient = coefficient;
  newNode->exponent = exponent;
  newNode->next = NULL;
   return newNode;
void insertTerm(Node** head, int coefficient, int exponent) {
  Node* newNode = createNode(coefficient, exponent);
```

```
if (*head == NULL || (*head)->exponent < exponent) {
        newNode->next = *head;
        *head = newNode;
      } else {
        Node* temp = *head;
        while (temp->next != NULL && temp->next->exponent > exponent) {
          temp = temp->next;
        if (temp->next != NULL && temp->next->exponent == exponent) {
          temp->next->coefficient += coefficient;
          free(newNode);
        } else {
          newNode->next = temp->next;
                                                                             241801282
          temp->next = newNode;
    Node* readPolynomial(int n) {
      Node* head = NULL;
      int coefficient, exponent;
      for (int i = 0; i < n; i++) {

#### 1. Problem Statement

Arun is learning about data structures and algorithms. He needs your help in solving a specific problem related to a singly linked list.

Your task is to implement a program to delete a node at a given position. If the position is valid, the program should perform the deletion; otherwise, it should display an appropriate message.

### **Input Format**

The first line of input consists of an integer N, representing the number of elements in the linked list.

The second line consists of N space-separated elements of the linked list.

The third line consists of an integer x, representing the position to delete.

Position starts from 1.

# **Output Format**

The output prints space-separated integers, representing the updated linked list after deleting the element at the given position.

If the position is not valid, print "Invalid position. Deletion not possible."

Refer to the sample output for formatting specifications.

```
Input: 5
82317
    Output: 8 3 1 7
    Answer
    #include <stdio.h>
    #include <stdlib.h>
    void insert(int);
   void display_List();
   void deleteNode(int);
   struct node {
      int data:
      struct node* next;
   } *head = NULL, *tail = NULL;
    void insert(int value){
      struct node*newnode=(struct node*)malloc(sizeof(struct node));
      newnode->data=value;
      newnode->next=NULL:

Section 1: Coding

#### 1. Problem Statement

Imagine you are working on a text processing tool and need to implement a feature that allows users to insert characters at a specific position.

Implement a program that takes user inputs to create a singly linked list of characters and inserts a new character after a given index in the list.

# **Input Format**

The first line of input consists of an integer N, representing the number of characters in the linked list.

The second line consists of a sequence of N characters, representing the linked list.

The third line consists of an integer index, representing the index(0-based) after

which the new character node needs to be inserted.

The fourth line consists of a character value representing the character to be inserted after the given index.

#### **Output Format**

If the provided index is out of bounds (larger than the list size):

- 1. The first line of output prints "Invalid index".
- 2. The second line prints "Updated list: " followed by the unchanged linked list values.

Otherwise, the output prints "Updated list: " followed by the updated linked list after inserting the new character after the given index.

Refer to the sample output for formatting specifications.

```
Input: 5
a b c d e
2
X
Output: Updated list: a b c X d e

Answer

Attempt : 1 Total Mark : 10 Marks Obtained : 10

Section 1: Coding

#### 1. Problem Statement

Dev is tasked with creating a program that efficiently finds the middle element of a linked list. The program should take user input to populate the linked list by inserting each element into the front of the list and then determining the middle element.

Assist Dev, as he needs to ensure that the middle element is accurately identified from the constructed singly linked list:

If it's an odd-length linked list, return the middle element. If it's an evenlength linked list, return the second middle element of the two elements.

### **Input Format**

The first line of input consists of an integer n, representing the number of elements in the linked list.

The second line consists of n space-separated integers, representing the elements of the list.

### **Output Format**

The first line of output displays the linked list after inserting elements at the front.

The second line displays "Middle Element: " followed by the middle element of the linked list.

Refer to the sample output for formatting specifications.

```
Sample Test Case
```

```
Input: 5
10 20 30 40 50
Output: 50 40 30 20 10
Middle Element: 30
Answer
#include <stdio.h>
#include <stdlib.h>
struct Node {
  int data;
struct Node* next;
// You are using GCC
Node*push(struct Node*head,int data)
  struct Node*newnode=(struct Node*)malloc(sizeof(struct Node));
  newnode->data=data:
  newnode->next=head;
  return newnode;
int printMiddle(struct Node*head){
  struct Node*slow=head,*fast=head;
```

```
while(fast!=NULL && fast->next!=NULL){
    slow=slow->next;
     fast=fast->next->next;
  return slow->data;
int main() {
  struct Node* head = NULL;
  int n;
  scanf("%d", &n);
                                                                            241801282
  int value;
 for (int i = 0; i < n; i++) {
     scanf("%d", &value);
    head = push(head, value);
  }
  struct Node* current = head;
  while (current != NULL) {
     printf("%d ", current->data);
     current = current->next;
  printf("\n");
int middle_element = printMiddle(head);
  printf("Middle Element: %d\n", middle_element);
  current = head;
  while (current != NULL) {
     struct Node* temp = current;
     current = current->next;
     free(temp);
                                                 241801782
  return 0;
Status: Correct
